## PI ReToF-MS TPD measurements of unirradiated ices

To elucidate the reaction product(s), the TPD experiments were first conducted with unprocessed acetaldehyde and acetaldehyde-2,2,2-d<sub>3</sub> ices at a photon energy of 10.49 eV (Fig. S3). As acetaldehyde polymerizes at low temperatures, these experiments are necessary to probe potential (protonated) acetaldehyde clusters as well as other impurities of the acetaldehyde. Fig. S3 shows the desorption profiles of mass-to-charge ratios between 40 and 200 for temperatures ranging from 80 K to 320 K for these measurements. While the main impurity of acetaldehyde-d<sub>4</sub> is found at a mass-to-charge ratio of 64, most probably corresponding to a C<sub>2</sub>D<sub>4</sub>O<sub>2</sub> isomer, the only impurity all three samples have in common is found at mass-to-charge ratios of 117, 123, and 126 for CH<sub>3</sub>CHO, CD<sub>3</sub>CHO, and CD<sub>3</sub>CDO ices, respectively. These different masses indicate the empirical formula of the impurity to be C<sub>5</sub>H<sub>9</sub>O<sub>3</sub> (C<sub>5</sub>D<sub>6</sub>H<sub>3</sub>O<sub>3</sub> for acetaldehyde-2,2,2-d<sub>3</sub>), which points to a protonated cluster, e.g. of methylglyoxal (CD<sub>3</sub>COCHO) and acetaldehyde. Otherwise, no notable signals appear in the TPD profiles.

## Ratio determination for D<sub>2</sub>O + CH<sub>3</sub>CHO ice

Deuterium oxide and the acetaldehyde isotopologues were condensed onto the silver substrate through two separate gas deposition arms with partial pressures amounting to 3×10<sup>-8</sup> Torr and 3×10<sup>-9</sup> Torr for deuterium oxide and acetaldehyde, respectively. The thickness of the ice was determined to be 950 ± 50 nm by laser interference measurements. To determine the ratio of constituents in the ice, the integrated absorption of each acetaldehyde IR absorption feature shown in Fig. S6 was compared to that of the 500 nm thick neat acetaldehyde ice to determine the column density and corresponding thickness of the acetaldehyde in the ice. In this analysis the absorption peak at 1720 cm<sup>-1</sup> was neglected as it changed drastically in shape in the mixed ice and its evaluation lead to a thickness more than twice of that derived from any other absorption feature. This analysis lead to a thickness of 220 ± 30 nm for acetaldehyde and correspondingly 730 ± 60 nm for deuterium oxide. Assuming densities of 0.78 g cm<sup>-3</sup> and 1.05 g cm<sup>-3</sup> for acetaldehyde and deuterium oxide, respectively, this translates to column densities of (2.3 ± 0.3)×10<sup>17</sup> molecules cm<sup>-1</sup> and (2.3 ± 0.2)×10<sup>18</sup> molecules cm<sup>-1</sup>, respectively, corresponding to a ratio of (10±1):1.

### **Formation of acetaldehyde oligomers**

Upon irradiation, oligomers of acetaldehyde molecules form. In the experiments reported here they consist of up to four acetaldehyde molecules and are detected at  $m/z = 94$ ,  $m/z = 141$ , and  $m/z = 188$  with decreasing signal strength as molecular mass grows. Additionally, strong signals can be seen at  $m/z = 95$ ,  $m/z = 142$ , and  $m/z = 189$ , corresponding to protonated acetaldehyde oligomers. The abundance of protonated oligomers in electron irradiated acetaldehyde ice also provides evidence of the suppressed formation of the vinoxy radical, which releases deuterium compared to the formation of the acetyl radical, which releases hydrogen. If both radicals formed at roughly equal abundance, this would be reflected in the relative amounts of protonated and deuteronated oligomers assuming these radicals to be the main source of hydrogen and deuterium. However, protonated acetaldehyde dimers ( $m/z = 95$ ) are detected at a much higher signal strength than the deuteronated dimers ( $m/z = 96$ ), the latter amounting to 9% of the signal at mass 95, as shown in Fig. S7. The deuterium needed to form the deuteronated dimers could be provided by release in the formation of ketene-d<sub>2</sub> (CD<sub>2</sub>CO).

### **Formation of acetone**

Another radical-radical reaction product detected in the TPD experiment is acetone-d<sub>6</sub> (CD<sub>3</sub>COCD<sub>3</sub>) at  $m/z = 64$ , as shown at 10.49 eV in Fig. S8. To validate the empirical formula, the desorption profile of  $m/z = 58$  of irradiated acetaldehyde ice is also shown. Acetone can form from the reaction of the acetyl radical (CD<sub>3</sub>·CO) with the methyl (·CD<sub>3</sub>) radical:

As seen for the diacetyl, the same desorption profile is also detected at  $m/z = 63$  at about 20% signal strength and at  $m/z = 62$  with even lower signal strength, which is another indication of H/D exchange in the sample. Again, no additional desorption event is seen at  $m/z = 63$  for propionaldehyde (CD<sub>3</sub>CD<sub>2</sub>CHO) which forms in the reaction of the methyl and the vinoxy radical.

Similar to the formation of diacetyl, the formation of acetone from acetaldehyde is endoergic, but steps (3b) and (4) are both exoergic.

Even though the formation of the methyl radical should also produce the formyl radical ( $\text{H}\dot{\text{C}}\text{O}$ , step 3a above), no reaction products involving the formyl radical are detected. As the recombination of the acetyl and the formyl radical is exoergic and proceeds barrierless, this indicates that either the formyl radical exclusively reacts with hydrogen to form carbon monoxide and molecular hydrogen, which is endoergic ( $\Delta_{\text{R}}G = -373 \text{ kJ mol}^{-1}$ ), that the formation of methyl only proceeds from the acetyl radical to directly form methyl and carbon monoxide (step 3b), or that triple fragmentation to methyl, hydrogen and carbon monoxide is the dominating channel as seen in the gas phase photolysis experiments at 248 nm<sup>[1]</sup>.

**Table S1.** Data used to calculate the irradiation dose of acetaldehyde-2,2,2-d<sub>3</sub> (CD<sub>3</sub>CHO)

<b>irradiation current, I (nA)</b>	<b>15 ± 2</b>
<b>initial kinetic energy of the electrons, E<sub>init</sub></b>	<b>5 keV</b>
