Experimental Procedures**Crossed molecular beams**

The gas-phase reactions of the 1-propynyl radical (CH_3CC ; $X^2\text{A}_1'$) with 2-methyl-1,3-butadiene ($\text{CH}_2\text{C}(\text{CH}_3)\text{CHCH}_2$; $X^1\text{A}'$) and 1,3-pentadiene ($\text{CH}_3\text{CHCHCHCH}_2$, $X^1\text{A}'$) were carried out under single-collision conditions using the crossed molecular beams machine.^[1,2] The crossed beams apparatus consists of two fixed orthogonal source chambers (primary and secondary), the main scattering chamber, and an ultrahigh-vacuum (UHV; 10^{-12} Torr), rotatable, differentially pumped detector. In the primary source chamber, the pulsed supersonic beam of 1-propynyl radical was generated by photodissociation of 1-iodopropyne (CH_3CCI ; TCI, 99%+) seeded at a level of 0.5% in helium (99.9999 %, Matheson), using the focused 193 nm output of the excimer laser (Coherent, CompEx110; 20 mJ pulse⁻¹; 30 Hz).^[3–5] The secondary molecular beam was produced using 2-methyl-1,3-butadiene ($\text{CH}_2\text{C}(\text{CH}_3)\text{CHCH}_2$; Sigma, 99%) or 1,3-pentadiene (*cis*- and *trans*- mixture of $\text{CH}_3\text{CHCHCHCH}_2$; TCI, >96.0%) released by Proch-Trickl pulsed valve^[6] at backing pressures of 430 Torr and 350 Torr, respectively. A four-slot chopper wheel located after the skimmer selected a part of the 1-propynyl radical beam with a well-defined peak velocity (v_p) and speed ratio (S) that intersected in the interaction region of the scattering chamber with the secondary beams. The peak velocities (v_p), speed ratios (S), center-of-mass angles (Θ_{CM}), and collision energies (E_c) of the hydrocarbons beams are summarized in Table S1. We should note that it is possible that the propargyl radical (2-propynyl, CH_2CCH) may be produced during generation of 1-propynyl by photodissociation of CH_3CCI via isomerization through hydrogen shift in the 1-propynyl radical in the photolysis zone, too. However, the entrance barrier for the addition of the propargyl radical to the diene moiety was shown to be about 80 kJ mol⁻¹,^[7] which is well above the collision energy in our experiments (43 ± 2 kJ mol⁻¹). Therefore, even if propargyl is present in the molecular beam, it will not contribute to the reactive scattering signal.

The scattering products of collision events are ionized by electron impact at 80 eV (2 mA) at the entrance of the rotatable detector, filtered according to mass-to-charge (m/z) ratios using the QMS (Extrel, QC 150; 1.2 MHz) and then detected using a Daly-type particle ion counter.^[8] The pulse scheme of the experiment is represented in Figure S1. Angular resolved time-of-flight (TOF) spectra were recorded in the plane of the reactant beams at discrete laboratory angles, which were integrated and normalized with respect to TOF at Θ_{CM} to extract the laboratory angular distribution (LAD). TOF and LAD were fit using a forward-convolution routine that is constrained by the reactant beam divergences, velocity spreads, and various machine parameters. This is an iterative method where user-defined center-of-mass (CM) translational energy ($P(E_T)$) and angular ($T(\theta)$) flux distributions simulate the measured signal under our experimental conditions.^[9,10] CM functions are varied until a suitable fit of the TOF spectra and LAD is achieved. Together, the CM functions represent the reactive differential cross section $I(\theta, u)$, which can be divided into components of the CM scattering angle θ and the CM velocity u , $I(u, \theta) \sim P(u) \times T(\theta)$, which is represented as a flux contour maps (Fig. 2) and reveals an overall image of the reaction outcome.

Sample preparation

Samples of 1-iodopropyne (CH_3CCl ; TCI, 99%+), 2-methyl-1,3-butadiene ($\text{CH}_2\text{C}(\text{CH}_3)\text{CHCH}_2$; Sigma, 99%), and 1,3-pentadiene (cis- and trans- mixture of $\text{CH}_3\text{CHCHCHCH}_2$; TCI, >96.0%) were purified by several cycles of freeze-pump-thaw method. 1-iodopropyne (CH_3CCl ; TCI, 99%+) was then diluted at a level of 0.5% in helium (99.9999%; Matheson) in a Teflon-coated sample cylinder (Swagelok); teflon coating is recommended to prevent sample degradation over time. This mixture was used at backing pressure of 760 Torr in the primary chamber pulsed valve. Neat 2-methyl-1,3-butadiene and 1,3-pentadiene were fed into the secondary chamber pulsed valve at backing pressures of 450 Torr and 400 Torr, respectively.

Electronic structure calculations

Geometry optimization of different structures on the C_8H_{11} potential energy surface (PES) accessed by the reactions of the propynyl radical with two C_5H_8 isomers, 2-methyl-1,3-butadiene (isoprene) and 1,3-pentadiene, was carried out at the density functional $\omega\text{B97X-D}$ level of theory^[11] with the 6-311G(d,p) basis set. Vibrational frequencies for all optimized stationary points were computed at the same $\omega\text{B97X-D}/6\text{-}311\text{G(d,p)}$ level. The calculations of frequencies allowed us to characterize all structures as either local minima or transition states and to evaluate zero-point vibrational energy corrections (ZPE). The frequencies were also used for calculations of energy-dependent rate constants. Single-point energies for each stationary point on the PES were rectified using the G3(MP2,CC) model chemistry scheme in which the coupled cluster CCSD(T)/6-311G(d,p) energy is upgraded by a basis set correction to the G3Large basis set evaluated at the Moller-Plesset second-order perturbation theory (MP2) level.^[12-14] The resulting G3(MP2,CC)/ $\omega\text{B97X-D}/6\text{-}311\text{G(d,p)} + \text{ZPE}(\omega\text{B97X-D}/6\text{-}311\text{G(d,p)})$ relative energies are known to be typically accurate within 10 kJ mol⁻¹ or better.^[14] The GAUSSIAN 09^[15] and MOLPRO 2015^[16] program packages were employed for the electronic calculations.

Calculations of energy-dependent rate constants

Rice-Ramsperger-Kassel-Marcus (RRKM) theory^[17–19] was employed to compute microcanonical, internal energy-dependent rate constants of all unimolecular reaction steps on the C₈H₁₁ PES following the initial association of the H₃CCC radical with the C₅H₈ isomers. We utilized our in-house code Unimol^[20] to evaluate the rate constants as functions of the available internal energy of each intermediate or transition state within the harmonic approximation. Unimol is an updated version of our previous software code on energy dependent RRKM calculations of rate constants for multiwell and multichannel unimolecular reactions under single-collision conditions and for solving a system of first-order kinetic equations.^[21] The internal energy in these calculations is assumed to be equal to the sum of the collision energy and the chemical activation energy, that is, negative of the relative energy of a species with respect to the reactants. Since the calculations simulate the experimental crossed molecular beams conditions at a zero-pressure limit, only one energy level is considered throughout. With all RRKM rate constants in hand, product branching ratios are then computed by solving first-order kinetic equations within steady-state approximation. The calculated rate constants and product branching ratios depending on the initial reaction intermediate formed by recombination of the reactants are presented in Supporting Information (Tables S9-S10 and S2-S8, respectively).
